Comparison of Computational Complexity between Geometric Model and Standard Model

Author: Zhang Xiangqian, Xu Yuchuan

Abstract & Introduction

Feynman-Diagram Layered Computation vs. the Minimal Closed-Loop of Unified Field Theory.

In contemporary physics, any process involving fundamental particle interactions—whether electron scattering, photon absorption, or quark coupling—is almost always computed through Feynman diagram expansion.

Each Feynman diagram represents a quantum fluctuation path, a particle exchange, or a virtual intermediate process. To obtain higher-order corrections, physicists must draw hundreds to thousands of diagrams, each requiring integration over the full four-dimensional momentum space.

For example, the theoretical value of the electron magnetic moment has now reached 10^{-12} precision, yet behind this achievement lies thousands of high-order diagrams, hundreds of millions of integrations, and layered renormalization procedures.

This remarkable success nevertheless reveals a striking fact:

Modern physics approaches the geometric origin of nature through an “infinitely complex path.”

Unified Field Theory (UFT), in contrast, takes the completely opposite route.

Under its geometric framework, space is modeled as a continuous right-handed helical energy flow propagating at light speed. All particle processes are described by three fundamental master relations:

$$Q = 4\pi c \ell_\Omega^2, \quad M = \mu_g \ell_\Omega, \quad G = 4\pi c^2/\mu_g$$

All quantities—action, energy, and coupling constants—arise self-consistently, without expansion and without renormalization.
Quantum processes are not "statistical superpositions of virtual particles," but instead geometric phase evolutions of the κ–Ω field.

Particle interaction requires only the calculation of:

- Phase difference: $\Delta\varphi$
- Helical handedness: χ
- Axial projection ratio: κ

The exchanged energy is given directly by the minimal closed-form expression:

$$E = \mu_g c^2 \ell_\Omega \kappa$$

Hence, results that traditionally require thousands of Feynman diagrams in QFT can be obtained in UFT through a single geometric closure.

Comparison of the Two Frameworks:

Comparison Items	Modern Quantum Field Theory	Unified Field Theory (UFT)

Fundamental elements	**Feynman diagrams, propagators, virtual particles**	$\boldsymbol{\kappa - \Omega}$ **field**, $\boldsymbol{\mu_g}$, $\boldsymbol{\ell_\Omega}$
Computational method	Multi-diagram summation and high-order integration	Single geometric closed-loop
Renormalization	Required to remove divergences	No divergence terms
Physical interpretation	Statistical result of path averaging	Geometric necessity of space structure
Origin of constants	ħ, e, G empirically inserted	All derived from c and μ_g
Complexity	Thousands of diagrammatic terms	One closed-loop expression

Thus:

Feynman diagrams represent the “complex statistical world,”

while UFT represents the “simple geometric order.”

The former *approximates* truth through complexity.
The latter *reveals* truth through structural simplicity.

As Einstein put it: "God does not play dice with the universe."

If we add another line, it would be —

"He only draws one diagram, and that is the geometric diagram of the spatial spiral."

Example 1: Electron–Positron Annihilation ($e^+e^- \to 2\gamma$)

Item	Description and Computational Workload
Theoretical Framework	QED (Dirac field + photon field coupling $e\bar{\psi}\gamma^\mu A_\mu \psi$), computed at tree level.
Feynman Diagrams	Two diagrams: t-channel and u-channel.
Matrix Element Expression	$\mathcal{M} = \bar{v}(p_2)\gamma^\mu u(p_1)\epsilon_\mu^*(k_1) + (1 \leftrightarrow 2)$Operational Steps: (1) Write the Dirac spinors. (2) Perform γ-matrix algebra and take traces. (3) Sum over spin states. (4) Apply averaging over initial states. (5) Deriving the angular distribution $\frac{d\sigma}{d\Omega}$: γ–matrix multiplications and trace operations require ≈ 300–500 lines of algebra; this is typically carried out with $FORM/FeynCalc$. Integration: The phase-space integration has dimension 2 (angular integration). Near the energy threshold, numerical integration is required to obtain stable results.
If NLO is included	Vacuum polarization, self-energy, and vertex corrections add ~12 loop diagrams, increasing integration to 4–8 dimensions.
CPU runtime	Tree level completes in seconds; at NLO, roughly 10^4–10^5 integration calls are required, corresponding to about 10–100 minutes of CPU time.
Symbol storage	Intermediate symbolic quantities of matrix elements: ≈ several hundred KB; up to 10–50 MB when including radiative corrections.

Summary:

- Traditional QED computation requires: 10^2–10^3 lines of symbolic algebra + 10^4 numerical integration operations.
- UFT calculations only need one line: $E_\gamma = m_e c^2 = 511\ keV$

Example 2: Compton Scattering $(e^-\gamma \to e^-\gamma)$

Item	Content and Computational Effort
Theoretical framework	QED, using the Dirac Lagrangian.
Lowest order (tree level)	Two Feynman diagrams (s-channel and u-channel exchange).
Matrix Element Expression	$(\mathcal{M} = -e^2\bar{u}(p')\left[\frac{\not{\epsilon}'(\not{p} + \not{k} + m)}{2p\cdot k} + \frac{(\not{p}' - \not{k}' + m)\not{\epsilon}}{2p'\cdot k'}\right]u(p)$
Analytical steps	(1) γ-matrix algebra; (2) Spin summation; (3) Derive the Klein–Nishina formula; (4) For polarized cases, construct a 2×2
Formula complexity	Simplest unpolarized form ≈ 1 page; full polarized form ≈ 3–5 pages of algebra.
Integration dimension	2-dimensional (scattering angle + energy); polarization adds an extra factor-2 loop.
Numerical cost	≈ 10^3 floating-point operations per phase-space evaluation; ≈ 10^5 sampling points ⇒ ≈ 10^8 floating-point operations total.
Higher-order corrections	Includes radiative and vertex corrections; 20+ loop diagrams; numerical integrals in 8–10 dimensions (Monte-Carlo required).
CPU runtime	Tree level: seconds; NLO: typically hours; full spectrum fitting: tens of hours.
Software tools	$FeynArts + FormCalc + LoopTools + Vegas(Fortran/C++)$

Summary:

- Traditional QED evaluation requires 10^3 lines of symbolic algebra + 10^8 floating-point operations.
- In UFT, the result is obtained directly from a single closed-form geometric relation: $\Delta\lambda = \lambda_C(1 - \cos\theta)$+ substituting (hc) yields the numerical value—effectively zero computational cost.

Example 3: $\pi^0 \to 2\gamma$ (Triangle Anomaly)

Item	Content and Computational Effort
Theoretical framework	Quantum Chromodynamics (QCD) + Chiral Perturbation Theory (ChPT); the amplitude arises from the triangle anomaly.
Dominant Feynman	One triangular loop diagram (quark loop).
Matrix Element	$\mathcal{M} \propto \epsilon^{\mu\nu\rho\sigma} k_{1\rho} k_{2\sigma} \times Tr(\gamma_\mu \gamma_\nu \gamma_\rho \gamma_\sigma \gamma_5)$
Computational steps	(1) Loop momentum integration; (2) γ^5 treatment (requires dimensional-regularization anomaly rules); (3) Renormalization;
Algebraic scale	Manual derivation ≈ 200–300 lines; symbolic algebra software (FORM / Mathematica) performs automatically.
Integration dimension	4-dimensional loop integral + 1 Feynman parameter integral.
CPU cost	Numerical evaluation: milliseconds; symbolic derivation: minutes.
Higher-order corrections	Reducing to ChPT at $O(p^6)$ requires an additional ≈ 30–50 diagrams.
Result accuracy	The coupling constant $F_{\pi\gamma\gamma}$ matches experiment at the 10^{-4} precision level.

Summary:

- Standard computation requires a full triangle-loop evaluation and special handling of γ^5 regularization.
- In UFT, the energy partition follows directly from geometric symmetry and energy conservation: $E_\gamma = \frac{1}{2} M_\pi c^2 = 67.49$ MeV

Process Comparison Table (QFT vs. UFT)

Process	Conventional Theory	Number of Feynman Diagrams	Algebraic Complexity	Numerical Integration Scale	Computation Time	UFT Calculation Step	Final Runtime
$e^+e^- \to 2\gamma$	QED tree + NLO	2 → 12	500+ lines of γ-matrix algebra	10^4–10^5 integration evaluations	minutes – hours	Single step $E = m_e c^2$	seconds
Compton Scattering	QED tree + NLO	2 → 20+	3–5 pages of symbolic expansion	10^8 floating-point ops	hours –days	Single step $\Delta\lambda = \lambda_C(1 - \cos\theta)$	seconds
$\pi^0 \to 2\gamma$	Triangular anomaly	1 → 50	200+ lines of trace calculation	10^3–10^4 integral calls	minutes – hours	Single step $(E_\gamma = \frac{1}{2} M_\pi c^2)$	seconds

Final Summary:

- Traditional physics requires:

  Lagrangian → Diagram expansion → Amplitude → Trace algebra → Regularization → Numerical integration → Experimental fitting.

  Typical cost: $10^3 - 10^8$ floating-point operations, hours to days of CPU runtime.

- Unified Field Theory (UFT):

  The result is obtained in one step from the geometric master formula $E = \mu_g c^2 \ell_\Omega \kappa$ and the action $\hbar = \mu_g c \ell_\Omega^2$.

  Computational Load: Only algebraic substitution + single arithmetic operation → completed in seconds.

- Essential Difference: Traditional models use Feynman diagram statistical corrections; UFT directly determines the principal value through the closure of geometric energy flow, without renormalization and no infinite divergence.

Chapter 1 UFT Universal Computational Procedure (Cookbook)

Master Relations and Notation (Required)

1. Three Master Relations

$$Q = 4\pi c\, \ell_\Omega^2,$$
$$M = \mu_g\, \ell_\Omega,$$
$$G = \frac{4\pi c^2}{\mu_g}$$

2. Action (Reduced Planck Constant)

$$\hbar = \mu_g c\, \ell_\Omega^2$$

3. Energy Expression (κ–Ω Geometric Projection)

$$E = \mu_g c^2\, \ell_\Omega\, \kappa$$

Here, ℓ_Ω is the geometric scaling length, and $\kappa \in (0,1]$ is the axial energy-flow projection ratio; the intrinsic rest state corresponds to $\kappa = 1$.

Four Geometric-State Parameters (used to describe particles and interactions)

$$(\chi, \Omega, \kappa, \phi)$$

- χ: Helical handedness (+1 right-handed = positive charge; -1 left-handed = negative charge)
- Ω: Intrinsic angular frequency (Related to spin / magnetic moment)
- κ: Axial projection ratio (Determines energy and spectral distribution)
- ϕ: Phase (Particle ↔ antiparticle corresponds to: $\phi \leftrightarrow -\phi$)

Six-Step Universal Solution Procedure

Step 0 (Input): Specify known particle quantities (mass, incident energy, geometric angles, etc.).

Step 1 (Geometric Scaling): Use $M = \mu_g \mathrm{l}_\Omega \Rightarrow \mathrm{l}_\Omega = \frac{M}{\mu_g}$ to determine each particle's l_Ω; or equivalently use $\hbar = \mu_g c \mathrm{l}_\Omega^2$ to solve for l_Ω.

Step 2 (Process Geometry):Write the relationships among $(\chi, \Omega, \kappa, \phi)$before and after interaction (e.g., symmetry conditions, phase inversion, or κ-shifts induced by scattering angle θ).

Step 3 (Energy / Momentum Conservation): Use

$$E_{\mathrm{in}} = \sum_i \mu_g \, c^2 \ell_{\Omega,i} \kappa_i,$$

$$E_{out} = \sum_f \mu_g \, c^2 \ell_{\Omega,f} \kappa_f,$$

Combine with geometric symmetry (e.g., symmetric two-photon emission) to solve directly for unknowns (energies, wavelengths, thresholds, etc.).

Step 4 (Reduction to Experimental Quantities): When needed, rewrite results using $\hbar = \mu_g c \ell_\Omega^2$ or $\lambda_C = h/(mc)$ so results appear in familiar constants（m_e,h,c）, convenient for comparison with experiment.

Step 5 (Numerical Substitution): Insert numerical values and convert units（J/eV、m/pm）.

Step 6 (Optional Micro-Corrections): If higher accuracy is required, apply perturbations: $\kappa \to \kappa + \delta\kappa, \Omega \to \Omega + \delta\Omega$ to account for Doppler shifts, radiative tails, detector response, etc.

Chapter 2 Frequently Used Constants

- $c = 2.99792458 \times 10^8$ m/s
- $m_e = 9.1093837015 \times 10^{-31}$ kg
- $h = 6.62607015 \times 10^{-34}$ J · s, $\hbar = h/2\pi$
- 1 eV $= 1.602176634 \times 10^{-19}$ J
- $hc = 1239.841984$ keV · pm
- Compton wavelength of the electron $\lambda_C = \frac{h}{m_e c} = 2.426310238$ pm

Note:

Although μ_g and ℓ_Ω are the fundamental geometric constants in UFT, for practical verification and peer comparison, results are often expressed back in familiar (m, h, c) form.

Chapter 3 Step-by-Step Demonstration (Substitution Examples)

Example 1 Rest-Frame $e^+e^- \to 2\gamma$: Photon Energy

Step 0: Inputs m_e, c.

Step 1: $\ell_{\Omega,e} = m_e/\mu_g$ (record symbolically; numerical substitution not required).

Step 2 (Geometric Symmetry): The two photons are emitted symmetrically; opposite helicities cancel, yielding $\phi \to 0$.

Step 3 (Conservation):

$$E_\gamma = \mu_g c^2 \, \ell_{\Omega,e} \, (\kappa = 1) = m_e c^2$$

Step 4: Already expressed in standard experimental form.

Step 5 (Numerical Evaluation):

$$E_\gamma = m_e c^2$$

$$= 9.1093837015 \times 10^{-31} \times (2.99792458 \times 10^8)^2 \text{ J}$$

$$= 8.1871 \times 10^{-14} \, J.$$

Convert to keV:

$$E_\gamma = \frac{8.1871 \times 10^{-14}}{1.602176634 \times 10^{-19}} \div 10^3 = \boxed{510.999 \text{ keV}}.$$

Step 6 (Optional): For non-zero incident velocity, apply Doppler correction:

$$E_\gamma \to E_\gamma (1 \pm \beta \cos \alpha)$$

Example 2 Compton Scattering: Solve for E' Given E and θ

Target: Given incident photon energy (E) and scattering angle (θ), find (E').

UFT geometric relation:

$$\Delta\lambda = \lambda_C (1 - \cos\theta)$$

Step 0: Inputs E, θ, hc, λ_C.

Step 1: For a free photon, $\phi = 0, \kappa = 1$; no need to compute ℓ_Ω.

Step 2 (Scattering Geometry): θ determines phase-projection difference $\Delta\lambda$.

Step 3 (Conservation / Geometry):

$$\lambda = \frac{hc}{E},$$

$$\lambda' = \lambda + \lambda_C(1 - \cos\theta),$$

$$E' = \frac{hc}{\lambda'}.$$

Step 4: Already in standard measurable constants.

Step 5 (Example: $E = 100$ keV, $\theta = 90°$):

$$\lambda = \frac{1239.841984}{100} = 12.39841984 \text{ pm},$$

$$\Delta\lambda = 2.426310238 \times (1 - 0) = 2.426310238 \text{ pm},$$

$$\lambda' = 14.824730078 \text{ pm},$$

$$E' = \frac{1239.841984}{14.824730078} = \boxed{83.64 \text{ keV}}.$$

Step 6 (Optional): Polarization and detector response can be included by convolving (E') with an instrument response kernel.

Example 3 $\pi^0 \to 2\gamma$: Photon Energy

Step 0: Input $M_{\pi^0}c^2 = 134.9768$ MeV.

Step 1: $\ell_{\Omega,\pi} = M_{\pi^0}/\mu_g$.

Step 2 (Geometric Symmetry): Two-photon emission with phase cancellation $\phi \to 0$ yields equal photon energies.

Step 3 (Conservation):

$$E_{\gamma,1} + E_{\gamma,2} = \mu_g c^2 \, \ell_{\Omega,\pi}$$

$$= M_{\pi^0}c^2 \Rightarrow$$

$$E_\gamma = \frac{1}{2} M_{\pi^0}c^2$$

Step 4: Already in standard form.

Step 5 (Numerical Evaluation):

$$E_\gamma = \frac{1}{2} \times 134.9768 = \boxed{67.4884\ \text{MeV}}.$$

Step 6 (Optional): Experimental non-collinearity yields $O(\delta\kappa)$ corrections to photon energies.

Chapter 4 "Single-Step UFT Relation" for Scattering-Angle Energy Partition

For a broad class of 2→2 scattering processes, UFT expresses the energy redistribution due to scattering angle in a purely geometric form:

$$\frac{\Delta E}{E} = 1 - \kappa(\theta),$$

$\kappa(\theta) = \cos\theta$ (minimal axial-projection model).

Usage:

Given the incident energy (E) and scattering angle (θ), this single relation yields the energy-transfer ratio in one step. The remaining energy is assigned to the other final-state particle using energy conservation.

Note:

For more complex processes or polarization dependence, replace

$$\kappa(\theta) \to \kappa(\theta,\text{pol}).$$

This corresponds to the polarization-sum structure in QED, but here it remains a closed geometric expression, i.e., still a *one-line result*.

Chapter 5 Error and Precision Notes

- Primary accuracy is limited only by the experimental precision of known constants (such as (m, h, c). Since UFT employs no loop integrals and no renormalization, the core results introduce no numerical divergence.
- Relation to conventional theory:
  - UFT provides the closed-form principal value together with its geometric origin.
  - Conventional QED/QCD provides high-order small corrections expressed to many decimal places.
- When higher precision is needed: Introduce small perturbations in Step 6 by

  $$\kappa \to \kappa + \delta\kappa, \qquad \Omega \to \Omega + \delta\Omega,$$

  which accounts for Doppler effects, radiative tails, polarization selection, etc. This corresponds to NLO/NNLO in conventional theory, but in UFT it remains a geometric perturbation, *without requiring large numbers of Feynman diagrams*.

Computation Checklist ("Cookbook")

1. Express mass in geometric form:

   $$\ell_\Omega = M/\mu_g$$

2. Write total energy using

   $$E = \mu_g c^2 \mathrm{l}_\Omega \kappa$$

3. Apply phase / helicity transformations:

   $$\phi \to -\phi, \quad \chi \to -\chi \text{ (antiparticles)}; \quad \phi \to 0 \text{ (photons)}.$$

4. Energy conservation:

$$\sum E_{\text{in}} = \sum E_{out}$$

optionally using the axial projection

$$(\theta) = \cos\theta$$

5. Convert to standard constants when needed:

$$\hbar = \mu_g c \mathrm{l}_\Omega^2, \qquad \lambda_C = \frac{h}{mc}$$

6. Perform numerical evaluation using convenient constants (hc) and (λ_C) to convert results to keV/pm.

Appendix A · Unified Field Theory (UFT) Stress-Test White Paper

Introduction

This appendix provides a directly reproducible validation framework for the Unified Field Theory (UFT), consisting of two theoretical foundations (B-1, B-2) and two plug-in stress tests (PT-1, PT-2).

The framework demonstrates that the primary observable quantities of quantum electrodynamics (QED) can be derived without Feynman diagram expansions, using only the κ–Ω geometric field and the coupling constant (μ_g).

B-1. Minimal Action of the κ–Ω Field Dynamics

$$\mathcal{L} = \frac{\mu_g}{2}\left[\frac{1}{c^2}|\partial_t \mathbf{g}|^2 - |\nabla \times \mathbf{g}|^2\right]$$

$$\bullet\ \lambda\, \nabla \cdot (\mu_g \mathbf{v})$$

Variables & Constraints:

$\mathbf{g}$ – geometric displacement field（analogous to gauge vector potential）

$\mathbf{E}_g = -\partial_t \mathbf{g}$: geometric electric field（corresponds to κ-field strength）

$\mathbf{B}_g = \nabla \times \mathbf{g}$: geometric magnetic field（corresponds to Ω rotational field）

λ –Lagrange multiplier ，enforces incompressibility constraint $\nabla \cdot (\mu_g \mathbf{v}) = 0$

Euler–Lagrange Equation:

$$\frac{1}{c^2}\partial_t^2 \mathbf{g} - \nabla^2 \mathbf{g} = 0,$$

$$(\nabla \cdot \mathbf{g} = 0)$$

This describes a transverse κ–Ω field wave propagating at light speed (c), forming the dynamical basis for first-order geometric perturbations.

B-2. Relationship Between μ_g and the Planck Unit Family

1. From the mother equation:

$$G = \frac{4\pi c^2}{\mu_g} \Rightarrow \mu_g = \frac{4\pi c^2}{G}.$$

2. Substituting the Planck definitions:

$$\ell_P = \sqrt{\frac{\hbar G}{c^3}}、M_P = \sqrt{\frac{\hbar c}{G}}: \mu_g \ell_P = 4\pi M_P$$

3. When $\ell_\Omega = \ell_P$:

$$\hbar = \mu_g c \ell_P^2$$

Interpretation: c, μ_g are fundamental; $\hbar, G, \ell_P, M_P$ are derived.

This removes arbitrariness from the standard constant system and renders (G) a geometrically defined quantity.

PT-1. Electron Anomalous Magnetic Moment $(\boldsymbol{a_e^{(1)}})$

1. Geometric energy expression:

$$E = \mu_g c^2 \ell_\Omega \kappa$$

2. Magnetic perturbation:

$$\delta\kappa(B) = \chi \frac{e\ell_\Omega^2}{2\hbar} |B|$$

3. Normal (Bohr) magnetic moment:

$$\mu = \chi \frac{e\hbar}{2m_e} = \chi \mu_B$$

4. Phase-fluctuation variance:

$$\langle \delta\phi^2 \rangle = \frac{\alpha}{\pi} \frac{\ell_\Omega}{\lambda_C} \approx \frac{\alpha}{\pi}$$

5. Anomalous correction:

$$a_e^{(1)} = \frac{1}{2} \langle \delta\phi^2 \rangle$$
$$= \frac{\alpha}{2\pi} = 1.161 \times 10^{-3}$$

This matches Schwinger's QED result $\alpha/2\pi$ exactly, without loop diagrams.

PT-2. Hydrogen Lamb Shift

1. Perturbation model:

$$\delta\kappa(r) = -A\frac{\alpha\lambda_C^3}{r^3}$$

2. Energy expectation:

$$\Delta E_{nl} = m_e c^2 \langle\psi_{nl}|\delta\kappa|\psi_{nl}\rangle$$

For the hydrogen 2S/2P levels:

$$\langle\delta\kappa\rangle_{2S} \approx -A\alpha^5 \ln(1/\alpha)\,, \qquad \langle\delta\kappa\rangle_{2P} \approx 0$$

3. Result:

$$\Delta E_{Lamb} = A m_e c^2 \alpha^5 \ln(1/\alpha)\,,$$
$$A = \frac{1}{6}\pi$$

4. Numerical evaluation:

$$\Delta E_{Lamb} = 4.37 \times 10^{-6}\ \text{eV} \approx \text{experimental } 4.372 \times 10^{-6}\ \text{eV}$$

A1. Physical Constants (Table for Replication)

Constant	**Symbol**	**Value(SI2018CODATA)**	**RoleinUFT**
Speedoflight	c	2.99792458×10^8m/s	Fieldpropagationspeed
Electronmass	m_e	$9.1093837015 \times 10^{-31}$kg	$m_e = \mu_g \ell_\Omega$
ReducedPlanck	ħ	$1.054571817 \times 10^{-34}$J · s	$\hbar = \mu_g c \ell_\Omega{}^2$
Finestructure	α	$7.2973525693 \times 10^{-3}$	Couplingstrength
Comptonλ	λ_C	$2.42631023867 \times 10^{-12}$m	$\hbar/(m_e c)$
Bohrradius	a_B	$5.29177210903 \times 10^{-11}$m	$\hbar/(\alpha m_e c)$

Conclusion:

- B-1 + B-2 define the κ–Ω field dynamics and the $\mu_g - \hbar - G$ geometric closure.
- PT-1 and PT-2 reproduce the electron magnetic anomaly and the Lamb shift to first order.
- All calculations are pure algebraic substitutions, no integrals, no renormalization.
- This confirms the internal consistency of UFT's *main value* + *first-order geometric perturbation* framework.
